SUBJECT: CALIFORNIA HIV SEROPREVALENCE ANNUAL REPORT, 1999

I am pleased to make available to you the California HIV Seroprevalence Annual Report. The data in this report were gathered in 1999 by the California Department of Health Services, Office of AIDS, in collaboration with local health departments, the Centers for Disease Control and Prevention, California blood banks and plasma centers, the United States Department of Defense, the California Department of Health Services, Genetic Disease Branch and Viral and Rickettsial Disease Laboratory.

The data have been useful to many local health departments in monitoring the human immunodeficiency virus (HIV) epidemic locally, targeting prevention activities and other services, and making other public health policy decisions.

I hope you find the data useful in your local HIV serosurveillance activities as well as the community HIV prevention planning process. If you have any questions about this annual report, please contact Donna Zukowski or Juan D. Ruiz, M.D., Dr. P.H. at (916) 324-8441.

Michael Montgomery, Chief  
Office of AIDS

## ACKNOWLEDGEMENTS

The California Department of Health Services, Office of AIDS thanks the following people for sharing their time and expertise during the development of this report:

Marilyn Mitchell, Fresno County Health Services Agency; David K. Martin, Kern County Health Department; Trista Bingham, County of Los Angeles Department of Health Services; Jesus Garcia, County of Sacramento Department of Health and Human Services; Alexander Taylor, County of San Bernardino Department of Public Health; Dr. Michele M. Ginsberg, County of San Diego Department of Health Services; Dennis Ferrero, San Joaquin County Public Health Services; Kavita Thirumalai, Santa Clara County Department of Public Health; Dr. Hazel G. Wallace, City of Long Beach Department of Health and Human Services; and Leroy Blair, City of Berkeley Department of Health and Human Services.

Additionally, special acknowledgement is given to the following persons:

Tim Kellogg, San Francisco Department of Public Health; Bob Poindexter, AIDS Case Registry Section, Office of AIDS; and Duncan MacKellar, Centers for Disease Control and Prevention.

## CALIFORNIA HIV SEROPREVALENCE ANNUAL REPORT, 1999

### I. EXECUTIVE SUMMARY

**Objectives.** The objectives of this project were: 1) to establish baseline HIV seroprevalence rates, and 2) to monitor HIV trends in known high-risk or cross-over groups.

**Design.** The serosurvey uses anonymous, unlinked (blinded) HIV testing. Blinded samples are gathered from discarded blood originally collected from consecutive eligible clients for routine diagnostic purposes and tested for HIV antibodies after all personal identifying information has been removed.

**Result.** During 1999, there were a total of 17,620 serum samples tested from clients attending Sexually Transmitted Diseases (STD) clinics, of which 601 (3.4%) were HIV antibody positive. Among risk categories, the highest HIV seroprevalence (27.0 %) was among men who reported sex with men who also injected drugs. Among racial/ethnic groups, prevalence was highest among White men (9.9%) and Black women (0.6%). Almost 28% (158/575) of all HIV-infected men was in age group 35-39, accounting for the highest prevalence of 9.8%. Age group 40-44 represented 16% (4/25) of all HIV-infected women, showing the highest prevalence of 0.9%. The highest HIV seroprevalences among clients attending STD clinics were reported from the counties of San Francisco and San Diego.

**Conclusion.** The anonymous seroprevalence survey among clients attending STD clinics has provided a basis for further describing the HIV epidemic among populations at greatest risk for HIV infection in selected areas of California.

# **CALIFORNIA HIV SEROPREVALENCE ANNUAL REPORT 1999**

## **Background**

Between 1988 and 1996, the California Department of Health Services, Office of AIDS (CDHS/OA) participated in Human Immunodeficiency Virus (HIV) Family of Surveys (HFS) funded by the Centers for Disease Control and Prevention (CDC). The CDHS/OA has funded sentinel serosurveillance activities from 1997 to the present. The objectives of sentinel serosurveillance are to: 1) provide state and local health officials and the general public with information on HIV prevalence in various populations, so that education and prevention programs can be developed, targeted, and evaluated; 2) indicate the magnitude and extent of HIV infection by demographic and behavioral subgroup and by geographic area; 3) indicate regional and national changes over time in the prevalence of infection in specific populations defined by risk behaviors and demographic characteristics; and 4) assist in projecting the number of children and adults who will develop HIV-associated illness and require medical care.

The serosurveys are clinic-based and are conducted annually in selected sentinel sites throughout the State. They are designed to establish baseline HIV seroprevalence rates, monitor HIV trends in known high-risk or cross-over groups, and serve as an early warning system for the possible spread of HIV from these groups into the general population.

All of these surveys use anonymous, unlinked (blinded) HIV testing. In unlinked surveys, samples gathered from discarded blood originally collected from consecutive eligible clients for routine diagnostic purposes are tested for HIV antibodies after all personal identifying information has been removed. The HIV test results as well as risk information obtained from medical records cannot be linked to specific individuals.

This summary presents results of the HIV serosurveillance activities from surveys in sentinel sites in California during 1999. The selected clinical settings are sexually transmitted disease (STD) clinics. In addition, this report includes data obtained from other sources: HIV screening by blood collection agencies of blood donations, HIV screening by the Department of Defense of civilian applicants for military service, and 1998 Survey of Childbearing Women data. In 1995 the CDC, at the request of the Assistant Secretary of Health and Human Services, discontinued the Survey of Childbearing Women. The CDHS/OA replicated this study during the third quarter of 1998 and performed Zidovudine (ZDV) determination on all HIV-positive specimens.

All of the surveys in this report measure HIV seroprevalence, which is the proportion of persons who have serologic evidence of HIV infection at a given time. Seroprevalence is influenced by the rate of new HIV infections (incidence) and by attrition of HIV-infected persons from the population under study, often through illness or death.

HIV seroprevalence is a good indicator of future morbidity and health delivery needs because it measures the level of HIV infection in a population. Seroprevalence data

from a single site should be interpreted with caution because the representativeness of the sample population may be changing.

## Highlights

### Sexually Transmitted Disease Clinics

In 1999, a total of 17,620 serum samples were tested for the presence of HIV antibody at 19 STD clinics in 11 local health departments<sup>1</sup> (Table 2). Statewide, the seroprevalence (3.4 percent) at STD clinics increased from 2.4 percent in 1998<sup>2</sup>.

The overall HIV seroprevalence among men in 1999 was 4.9 percent and among women was 0.4 percent (Table 3). By risk behavior, the highest seroprevalence (27.0 percent) in STD clinics was among men who reported sex with men who also injected drugs, up from 19.0 percent in 1998.

Among men in the sample, seroprevalence was highest (9.9 percent) in the White racial/ethnic group (Table 4). Among women, the Black racial/ethnic group had the highest seroprevalence (0.6 percent), down from 0.9 percent in 1998.

Figures 7-14 present trends in HIV seroprevalence among persons attending STD clinics in eight regions of California for years 1994–1999, by Race/Ethnicity, Age Group and Risk Behavior.

### California Blood Banks and Plasma Centers

In 1999, 721,055 specimens from selected California blood banks<sup>3</sup> were tested, of which 19 (0.003) percent were seropositive (Table 23). In 1999, 637,908 specimens from selected California plasma centers<sup>4</sup> were tested, of which 47 (0.007 percent) were HIV seropositive (Table 24).

### Civilian Applicants for Military Service

In 1999, a total of 19,049 serum samples were tested among persons applying for military service in nine selected counties<sup>5</sup>, of which five were HIV seropositive. HIV seroprevalence was 0.03 percent (Table 25).

<sup>5</sup>Fresno, Kern, Los Angeles, Sacramento, San Bernardino, San Diego, San Francisco, San Joaquin, Santa Clara.  
California Department of Health Services  
Office of AIDS, 2001

Men represented 80.7 percent of the total civilian applicants among these counties, of which 0.03 percent were HIV seropositive (Table 26). Women represented 19.3 percent with HIV prevalence of 0.03 (Table 27).

### Survey of Childbearing Women

During 1998, 76,166 specimens were tested among selected counties<sup>6</sup> for maternal HIV antibodies (Table 28). The seroprevalence rate was 0.08 percent.

By age group, women aged 35 & Over had the highest seroprevalence, followed by age group 25-29.

By race/ethnicity, Black women showed the highest (0.38 percent) seroprevalence rate (Table 29).

## **PROPOSED NON-NAME BASED HIV REPORTING SYSTEM IN CALIFORNIA**

The advents of new human immunodeficiency virus (HIV) treatments in recent years have drastically changed the nature of the HIV epidemic. These treatment advances have reduced morbidity and mortality among individuals infected with HIV and significantly delayed the progression of HIV to the most advanced stage of the disease, namely, acquired immunodeficiency syndrome (AIDS). Consequently, exclusive reliance on AIDS case surveillance information to monitor and characterize various aspects of the HIV epidemic will produce an incomplete picture of the HIV-infected population.

There is a compelling need to provide more accurate, complete and timely information on the HIV epidemic to assist in the development of effective education, prevention, early intervention, care and treatment programs. In response to this need, the State Office of AIDS (OA) has proposed new regulations (R-19-00) for the reporting of individuals infected with HIV. While maintaining the existing name-based surveillance methods for AIDS, the proposed regulations require providers of service and laboratories licensed to conduct HIV-related testing in California to report individuals with confirmed test results indicative of HIV infection to the appropriate local health departments using a non-name code. The local health departments shall, in turn, forward unduplicated HIV case reports to the OA using the non-name code.

The period for public comment for the proposed regulations began on March 30, 2001 and ended on May 21, 2001. The OA is currently reviewing the comments and making necessary revisions to the regulation. The proposed non-name-based surveillance system is tentatively scheduled for implementation during the later part of fiscal year 2001-2002.

# SEXUALLY TRANSMITTED DISEASE CLINICS

## **SURVEYS OF ADULTS ATTENDING SEXUALLY TRANSMITTED DISEASE (STD) CLINICS**

STD clinics serve persons at increased risk of infectious disease due to unprotected sex and other behaviors such as injection drug use. During 1999, STD clinics in 11 local health departments<sup>1</sup> conducted unlinked surveys to determine rates of HIV infection among adults attending STD clinics. Serum samples from clients who were being evaluated for a possible STD and who had not previously visited the clinic since initiation of the survey in any calendar year were included in the survey. Clients attending the clinic solely for HIV testing are eligible for the survey if they have blood drawn for purposes other than HIV testing. Eligible specimens were selected consecutively to meet a desired sample size of at least 500 clients at each clinic.

Beginning in 1997, revised data collection forms and software were implemented which included changes in Risk Behavior and Age Group categories.

STD clinics serve large numbers of HIV-infected persons. HIV surveillance in these clinics provides important information about populations at greatest risk for HIV infection. Serosurveillance may also provide an early warning of the heterosexual spread of HIV infection, since those at greatest risk of heterosexual transmission are likely to be those also at risk of acquiring other STDs.

This report summarizes results for 1999 from 19 STD clinics in selected California counties and cities. Statewide, the seroprevalence at the clinics increased from 2.4 percent in 1998<sup>2</sup> to 3.4 percent in 1999 (Table 1).

Selected California counties and cities submitted between 109 and 9,187 serum specimens each for a total of 17,620 serum samples tested during 1999 (Table 2).

HIV seroprevalence varied by region, from a high of 9.4 percent in San Francisco to a low of zero positives in the South Valley (Table 1, Figure 1). The seroprevalence for San Francisco, San Diego, Los Angeles, North Valley, Bay Area and Long Beach regions showed an increase from 1998. However, the seroprevalence for Central Valley decreased and South Valley remained the same. Among selected counties the highest percent increase between 1998 and 1999 was in Sacramento County.

Men represented 66.7 percent (11,753) of the total STD population of which 4.9 percent (575) were HIV seropositive, compared to 3.5 percent in 1998 (Table 3). Women represented 33.1 percent (5,831) of the total STD population of which 0.4 percent (25) were HIV seropositive, a decrease from 0.5 percent in 1998. The highest seroprevalence

---

<sup>1</sup> Fresno, Kern, Los Angeles, Sacramento, San Bernardino, San Diego, San Francisco, San Joaquin, Santa Clara, Long Beach, and Berkeley.

<sup>2</sup> All 1998 data from: State of California, Department of Health Services, Office of AIDS, HIV/AIDS Epidemiology Branch; California HIV Seroprevalence Annual Report 1998, August 2000.

(27.0 percent) was among men who reported sex with men who injected drugs, compared to 19.0 percent in 1998 (an increase of 42.1 percent). Men who have sex with men showed a prevalence of 19.1 percent, up from 16.5 percent in 1998. Among Heterosexuals, men showed a seroprevalence of 0.8 percent, and women showed a seroprevalence of 0.4 percent, both remaining the same compared to 1998.

In 1999, 37.0 percent (6,527) of the specimens tested in the STD clinics were drawn from Black clients; 34.9 percent (6,146) from Hispanics; 21.4 percent (3,776) from Whites; and 4.2 percent (735) from Asian/Pacific Islanders (Table 4, Figure 2). Seroprevalence for White men (9.9 percent) increased compared to 1998 (6.3 percent), however White women remained at 0.4 percent. Among Black men the seroprevalence showed an increase from 2.8 percent in 1998 to 3.3 percent in 1999. Black women showed a decrease from 0.9 percent in 1998 to 0.6 percent in 1999. The seroprevalence for both Hispanic men (3.2 percent) and Hispanic women (0.2 percent) decreased compared to 1998 (2.6 and 0.1 percent, respectively). The seroprevalence for Asian/Pacific Islander men (3.6 percent) and women (0.3 percent) decreased from 1998 (2.0 and 0.0 percent, respectively).

Age group 35-39 had the highest seroprevalence (9.8 percent) and represented 13.8 percent of men attending STD clinics (Table 5, Figure 3). Among women the seroprevalence for age group 40-44 was the highest (0.9 percent), and represented 7.8 percent of women attending STD clinics.

Table 6 and Figure 4 present HIV seroprevalence for men who have sex with men (MSM) and MSM who have a history of injection drug use (IDU) attending STD clinics by race/ethnicity. In 1999, HIV seroprevalence ranged from a high of 30.1 (84/279) percent among Black men to a low of 7.4 (7/94) percent among Asian/Pacific Islander men. By age group the highest seroprevalence (31.4 percent) was among age group 40-44 (Table 7).

Tables 8, 9 and Figure 5 present HIV seroprevalence for heterosexual males and females attending STD clinics by race/ethnicity. In 1999, the highest HIV seroprevalence was for Asian/Pacific Islander males (1.4 percent) and Black females (0.6 percent).

The highest seroprevalence (1.7 percent) among heterosexual males was in age group 35-39 (Table 10 and Figure 6). Among women, seroprevalence was 0.9 percent for age groups 35-39 and 40-44 (Table 11).

Tables 12 through 22 present seroprevalence data from the sentinel sites by risk behavior, race/ethnicity and age group.

<sup>1</sup> These unlinked (blinded) surveys were drawn from blood specimens collected for routine syphilis screening. Specimens were collected consecutively and tested for HIV after all personal identifiers were removed.

<sup>2</sup> North Valley= Sacramento. Bay Area= City of Berkeley and Santa Clara. Central Valley= Fresno, Kern, and San Joaquin. South Valley= San Bernardino.

<sup>3</sup> All positive specimens were repeatedly reactive by Enzyme-linked Immunosorbent Assay (ELISA) and confirmed by a Western blot or Immunofluorescence Assay (IFA).

<sup>4</sup> Data collection for July – December 1999.

<sup>5</sup> Data collection for January - June 1999.

Note: Region totals include unknown gender and may not agree with individual County/City totals (Tables 12-22).

<sup>1</sup>These unlinked (blinded) surveys were drawn from blood specimens collected for routine syphilis screening. Specimens were collected consecutively and tested for HIV after all personal identifiers were removed.

<sup>2</sup>All positive specimens were repeatedly reactive by Enzyme-linked Immunosorbent Assay (ELISA) and confirmed by a Western blot or Immunofluorescence Assay (IFA).

<sup>a</sup> Not calculated for fewer than 100 tested and number positive less than or equal to 3.

<sup>b</sup> Not applicable.

<sup>c</sup> Less than 5.

<sup>1</sup>These unlinked (blinded) surveys were drawn from blood specimens collected for routine syphilis screening on individuals seeking evaluation, examination, and/or for a new STD episode. Specimens were collected consecutively and tested for HIV after all personal identifiers were removed.

<sup>2</sup>All positive specimens were repeatedly reactive by Enzyme-linked Immunosorbent Assay (ELISA) and confirmed by a Western blot or Immunofluorescence Assay (IFA).

<sup>a</sup>Not applicable.

<sup>b</sup>Not calculated for fewer than 100 tested and number positive less than or equal to 3.

<sup>c</sup>Less than 5.

## **TRENDS IN HIV SEROPREVALENCE AMONG STD PATIENTS BY REGION 1994 - 1999**

Figures 7 through 14 present trends in HIV seroprevalence among persons attending sexually transmitted disease clinics in eight regions of California, 1994–1999.

In San Francisco, White patients had the highest HIV seroprevalence from 1994 through 1999. The prevalence of HIV infection peaked in 1999 for White and Black patients and in 1995 for Hispanic patients. White patients showed a steady decline of HIV infection between 1995 and 1998, rising sharply in 1999. Both Black and Hispanic patients showed a slight increase between 1996 and 1999. Patients aged 15-44 showed a slight decline for years 1995-1998 and a slight increase from 1998 to 1999. Seroprevalence for age group 45 & Over peaked in 1999. In all six years we see the same ranking for risk behavior: MSM IDU, MSM, Heterosexual IDU, and Heterosexuals. HIV seroprevalences fluctuated for MSM IDU, and remained steady for Heterosexuals and Heterosexual IDU patients. HIV seroprevalence among MSM patients declined through 1998, and slightly increased in 1999.

In San Diego, White patients had fluctuating HIV seroprevalences from 1994 through 1999. The prevalence of HIV infection peaked in 1997 for White and Hispanic patients and in 1999 for Black patients. Black patients showed an increase of HIV infection between 1996 and 1999. Both age groups (15-44 and 45 & Over) showed fluctuating HIV prevalence. MSM had the highest prevalence of HIV infection, declining sharply between 1997 and 1998, and rising sharply in 1999. The rates of HIV infection among heterosexual patients remained the lowest and steady.

In Los Angeles, White patients had the highest prevalence of HIV infection. HIV infection peaked in 1999. Both Black and Hispanic patients showed steady rates of HIV infection. Both age groups (15-44 and 45 & Over) had the highest prevalence of HIV infection in 1997. MSM and MSM IDU groups had the highest prevalence of HIV infection between 1994 and 1999. Both groups showed a decline in HIV infection in 1998. The rates among Heterosexuals and Heterosexuals IDU patients remained steady.

The Central Coast Region included the County of San Luis Obispo and the City of Long Beach for years 1994–1997 and City of Long Beach only for 1998-1999. The prevalence of HIV infection peaked in 1999 for Whites, in 1997 for Blacks and in 1998 for Hispanics. Both White and Black patients showed an increase of HIV infection in 1999; Hispanic patients had a sharp decline in 1999. Age group 15-44 years showed steady rates of HIV infection. Age group 45 & Over showed fluctuating rates of HIV infection. MSM had the highest prevalence of HIV infection, declining sharply from 1996 to 1998. The rate of HIV infection among Heterosexuals remained steady.

The Bay Area region includes the County of Santa Clara and the City of Berkeley. The prevalence of HIV infection peaked in 1995 for Black and White patients. All race/ethnicity groups showed an increase in HIV infection in 1999. Age group 15-44 years showed a

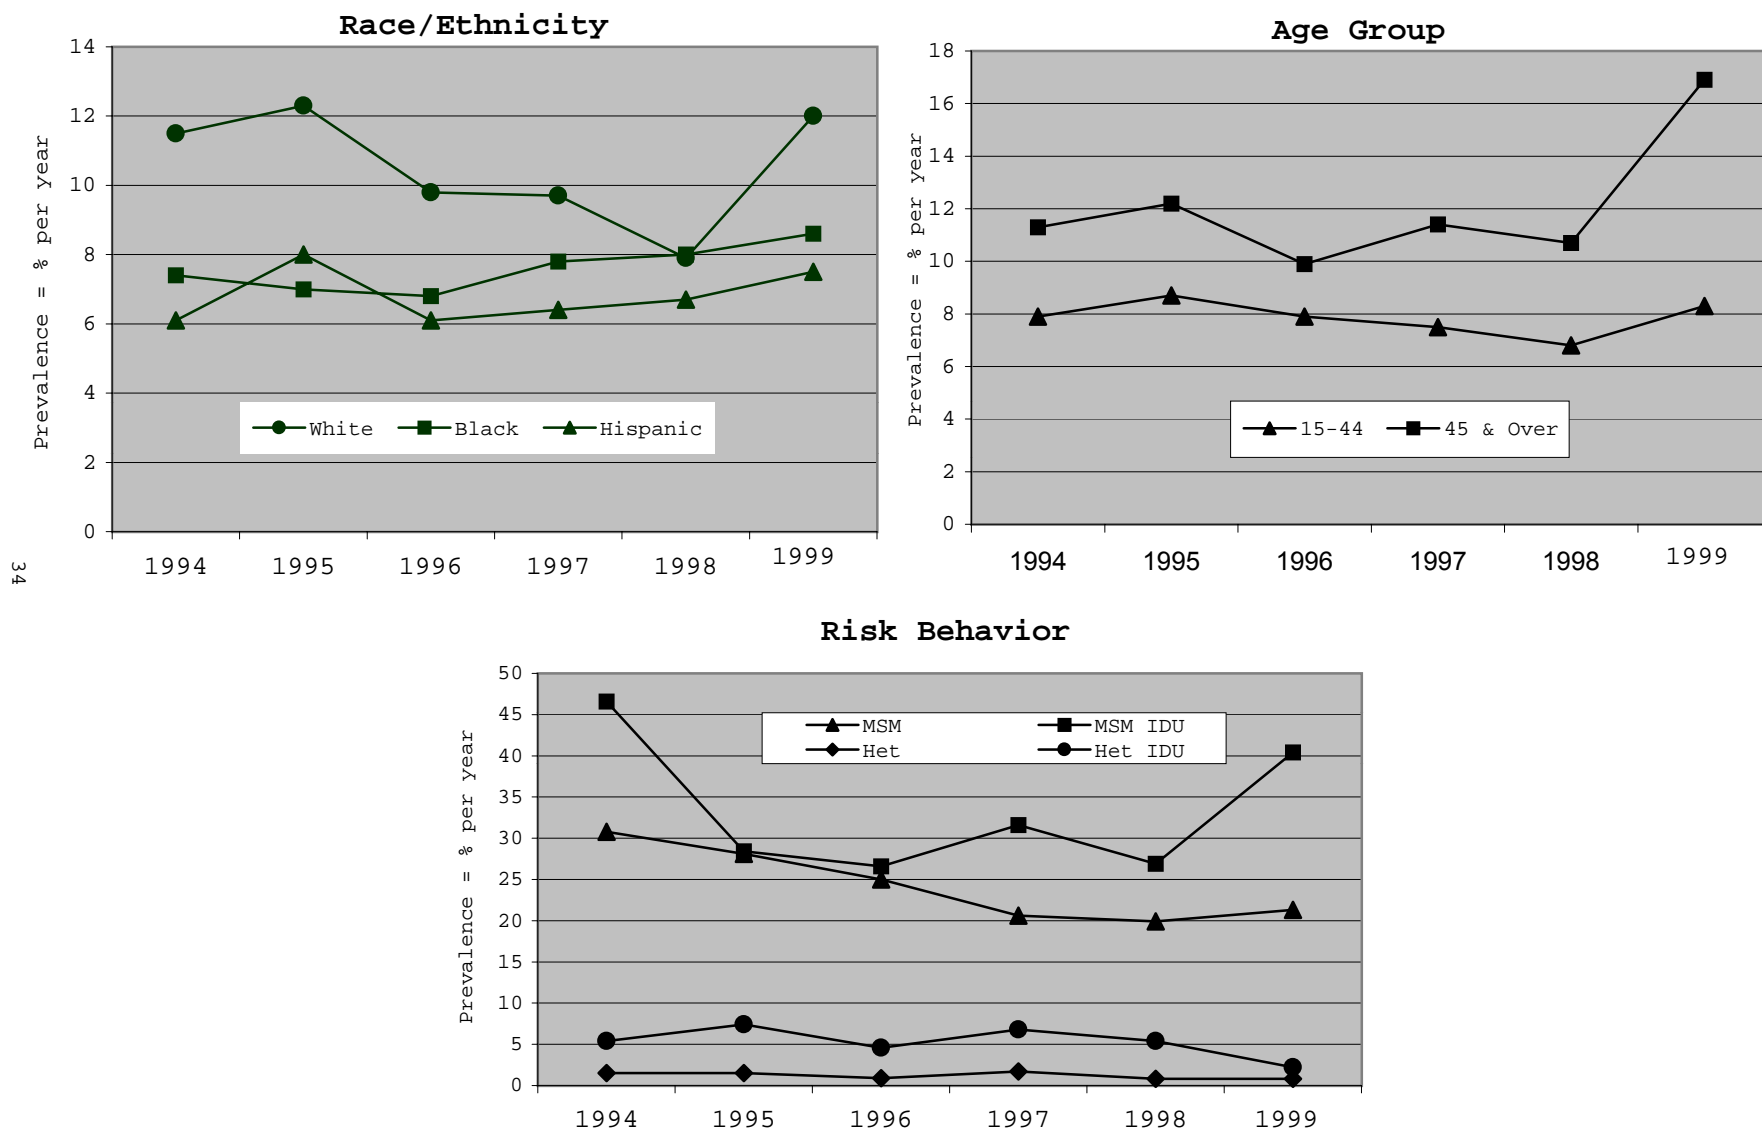

steady decline of HIV infection through 1998, showing an increase in 1999. Age group 45 and Over showed fluctuating rates of HIV infection. MSM had the highest prevalence of infection, declining from 1995 through 1998, and rising sharply in 1999. The rates of HIV infection among Heterosexual patients remained steady.

The Central Valley region includes the counties of Fresno, Kern, and San Joaquin. Black patients had the highest HIV seroprevalence, declining sharply from 1996 to 1997. White patients showed a steady decline through 1997, increasing slightly in 1998, and decreasing in 1999. Hispanic patients showed a decrease in HIV prevalence from 1994 through 1997, and rising slightly through 1999. Both age groups had the highest prevalence of HIV infection in 1994, and both age groups showed fluctuation in HIV prevalence. Heterosexuals had the highest prevalence in 1994, rising sharply from 1997 to 1998.

The North Valley region includes the counties of Sacramento and Solano for 1994 and 1995. Years 1996 through 1999 include Sacramento only. The prevalence of HIV infection peaked in 1999 for Whites and Blacks. Both White and Black patients showed fluctuating rates of infection, both showing an increase from 1997 to 1999. Age group 15-44 dropped sharply between 1996 and 1997, and peaked in 1999. Heterosexual patients showed fluctuating HIV prevalence, rising sharply between 1998 and 1999.

The South Valley region includes the counties of San Bernardino and Riverside counties for 1994 through 1996. HIV seroprevalence was highest among White patients. The prevalence of HIV infection peaked for Black and Hispanic patients in 1996 and in 1994 for White patients. Age group 15-44 peaked in 1994, declining through 1996. Heterosexuals had the highest prevalence in 1994, declining through 1996.

Source: California Department of Health Services, Office of AIDS.

**Figure 8. Temporal Trends in HIV Seroprevalence among STD Clinic Patients in San Diego Region, 1994 - 1999**

Note: Data were collected for six months only in all categories.

Note: For years 1995 through 1997, and 1999 there were less than 100 tested and less than or equal to 3 positive test results for age group 45 & Over.

Note: No information available for MSM IDU and Het IDU categories.

# BLOOD BANKS AND PLASMA CENTERS

## **SURVEY AMONG BLOOD BANKS AND PLASMA CENTERS**

The California Department of Health Services, Office of AIDS (CDHS/OA), began monitoring data from the routine testing of blood donors in 1987. HIV prevalences among donors are lower than those of the general population because persons at increased risk for HIV infection are actively discouraged from donating.

This report summarizes data from HIV-1 antibody screening of blood and blood products collected in selected California counties and cities for 1999. Additional county data are available through the Office of AIDS. CDHS/OA received reports of testing results from 40 blood banks and 10 plasma centers. This information represents data from California facilities required to report HIV-1/HIV-2<sup>1</sup> antibody test results to CDHS/OA. HIV-2 data are not included in this report.

In 1999, 721,055 specimens from selected California blood banks<sup>2</sup> were tested, of which 19 (0.003 percent) were seropositive. HIV seroprevalence in selected California blood banks ranged from zero to 0.005 percent (Table 23).

In 1999, 637,908 specimens from selected California plasma centers<sup>3</sup> were tested, of which 47 (0.007 percent) were seropositive (Table 24). HIV seroprevalence in selected California plasma centers ranged from zero to 0.013 percent.

---

<sup>1</sup>Testing for HIV-2 began the second quarter of 1992. Data collected through 1999 showed 25 (23 Blood Banks, 2 Plasma Centers) confirmed positive for HIV-2. To date, the U.S. Food and Drug Administration has not licensed a confirmatory test for HIV-2 infection. Currently, reactive HIV-2 EIAs are confirmed by unlicensed tests. Cross-reactivity between HIV-1 and HIV-2 is a strong possibility in instances where HIV-2 is confirmed by existing unlicensed testing.

# CIVILIAN APPLICANTS FOR MILITARY SERVICE

## **SURVEY AMONG CIVILIAN APPLICANTS FOR MILITARY SERVICE**

Since October 1985, all persons applying for active duty or reserve military service, the service academies, and the Reserve Officer Training Corps (ROTC) have been screened for HIV infection as part of their entrance medical evaluation. Applicants found to be HIV positive are excluded from military service but receive counseling from a military physician and referrals to HIV/AIDS specialists and counselors in their own communities. Data from this group are important because of the large number of persons screened and because the applicants include both sexes and all racial and ethnic groups from all areas of the country. The Department of Defense shares the resulting statistical data with the Centers for Disease Control and Prevention (CDC) for HIV surveillance purposes. The CDC in turn provides this information (excluding personal identifiers) to state and local health departments.

Prior to July 1993, before medical evaluations, applicants were interviewed about drug use and homosexual activity, both of which were grounds for exclusion from entry into military service. Potential applicants were informed that they would be screened for HIV antibodies and excluded from entry if infected. Therefore, injecting drug users, men who have sex with men, and persons who suspected or were already aware they were infected with HIV were likely to have been under represented among those applicants actually tested. In 1993, President Clinton authorized the “don’t ask, don’t tell policy” and applicants could no longer be asked about homosexual activity.

This report summarizes data for nine selected California counties<sup>1</sup> that also collect STD data. Additional county data are available through the Office of AIDS. In 1999, a total of 19,049 specimens from these selected counties were tested for HIV antibodies (Table 25). Of these, 0.03 percent were seropositive. Prevalence ranged from zero positives in five counties to a high of 0.37 percent in San Francisco county.

As shown in Table 26, males represented 80.7 percent (15,370) of the total civilian applicants for these counties, of which four (0.03 percent) were seropositive. Females represented 19.3 percent (3,679) of the total civilian applicants for these counties, of which one (0.03 percent) was seropositive (Table 27).

In 1999, men in age group 25-29 showed the highest prevalence of 0.08 percent. The one positive among women was in age group 15-19 with a prevalence of 0.04 percent.

Among race/ethnicity groups, Black men had the highest prevalence of 0.10 percent and Black women had one positive (0.14 percent).

# SURVEY OF CHILDBEARING WOMEN

## SURVEY OF CHILDBEARING WOMEN

From 1988 through 1995, an anonymous national HIV serosurvey – the Survey of Childbearing Women – was conducted to monitor prevalence of HIV infection among women delivering infants in the United States. The survey was based on the systematic, unlinked testing for HIV antibody with residual dried blood spot specimens routinely collected from newborns for routine metabolic screening.

CDHS/OA in collaboration with the Genetic Disease Branch (GDB) and the Viral and Rickettsial Disease Laboratory (VRDL), participated in this national serosurvey from 1988 through 1995. OA collected data on consecutive births during the third quarter (July, August, and September) of each year. In 1998, OA, in collaboration with GDB and VRDL, replicated the serosurvey. In addition, the Centers for Disease Control and Prevention (CDC) measured zidovudine in HIV antibody-positive specimens to assess the prevalence of zidovudine therapy among HIV-infected childbearing women. These population-based data are important to target resources in a cost-beneficial manner and to enhance HIV counseling and testing strategies among pregnant women.

This report includes HIV seroprevalence for childbearing women in selected California counties and cities<sup>1</sup>. During 1998, 76,166 unlinked specimens were tested for maternal HIV antibodies in these counties. Of these, 60 specimens were confirmed positive. The seroprevalence for childbearing women in selected California counties was 0.08 percent (eight per 10,000). County-specific seroprevalence ranged from zero positives in Santa Clara county and the City of Berkeley to a high of 0.26 percent in the City and County of San Francisco. Overall, among selected counties the prevalence of zidovudine therapy among HIV infected childbearing was 78.3% (47/60). Additional county data are available in California Childbearing Women: A Comparison of HIV Seroprevalence Data from the Third Quarters of 1992, 1995, and 1998 and Zidovudine Determination, 1998.

In 1998, age-specific HIV seroprevalences were highest among women in age groups 25-29 and 35 and Over. Women aged 19 and Under and “Unknown” had zero positives.

During the third quarter of 1998, among selected California counties and cities, Hispanic childbearing women accounted for the largest numbers of births (41,389). However, race-specific seroprevalences reveal substantially higher HIV seroprevalence among Black women. In 1998, seroprevalences were five times higher among Black women compared with White women, and eight times higher than Hispanic women.
